GONG: **Global Oscillation Network Group (http://gong.nso.edu/)**
Originally developed to study solar oscillations
6 observing stations worldwide observing the Sun 24/7
The six sites comprising the GONG Network are:
The Big Bear Solar Observatory in California, USA.
The High Altitude Observatory at Mauna Loa in Hawaii, USA.
The Learmonth Solar Observatory in Western Australia.
The Udaipur Solar Observatory in India.
The Observatorio del Teide in the Canary Islands.
The Cerro Tololo Interamerican Observatory in Chile.

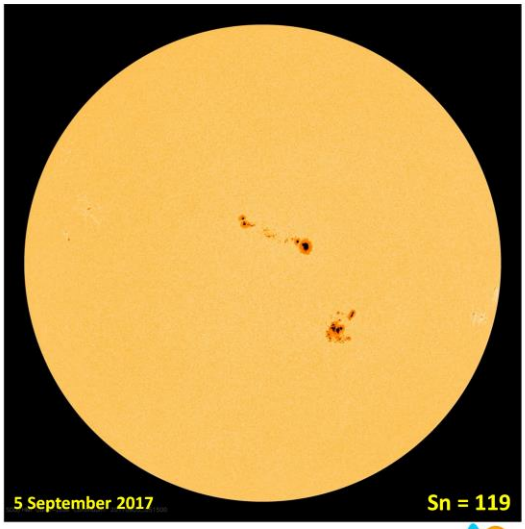
Provides coronagraphic imagery. Large data gaps

Sunspot number & Solar cycle

- Sunspot number
  - Sn
    - Also called International Sunspot Number (ISN)
  - Sn = 10.g + s,
    - with g the number of groups, and s the number of spots
  - Determined by the SIDC/SILSO (Uccle)!
    - http://www.sidc.be/silso
    - Network of about 80 stations



Links
SILSO: http://sidc.oma.be/silso/ (Sunspot Index and Long-term Solar Observations)
USET: http://www.sidc.be/uset/ (Uccle Solar Equatorial Table)
Catania: http://web.ct.astro.it/sun/draw.jpg

The International sunspot number is a quantity that measures the number of sunspots and groups of sunspots present on the surface of the sun.
It is computed from a number of international observers using the formula:

$$R = k (10 g + s)$$

where

s is the number of individual spots,
g is the number of sunspot groups, and
k is a factor that varies with location and instrumentation (also known as the observatory factor or the personal reduction coefficient). It is not to be computed or applied by the observer.

Sunspot number & Solar cycle

- Solar cycle
  - Avg. duration: +/- 11 years
    - Rise/Fall time: +/- 4 & 7 years
  - Avg. Sn_{max}: 184 (+/- 59)
    - SC24
      - Minimum: December 2008
      - Maximum: April 2014
      - Sn_{max} = 116.4
  - Butterfly diagram
    - Spots first appear at moderate latitudes (+/- 30°), then gradually move to equator
    - During SC minimum, groups of old and new SC exist

NOAA/SWPC glossary at https://www.swpc.noaa.gov/content/space-weather-glossary
Sunspot: An area seen as a dark spot, in contrast with its surroundings, on the photosphere of the Sun. Sunspots are concentrations of magnetic flux, typically occurring in bipolar clusters or groups. They appear dark because they are cooler than the surrounding photosphere. Larger and darker sunspots sometimes are surrounded (completely or partially) by penumbrae. The dark centers are umbrae. The smallest, immature spots are sometimes called pores.
Filaments/Prominences: A mass of gas suspended over the chromosphere by magnetic fields and seen as dark ribbons threaded over the solar disk. A filament on the limb of the Sun seen in emission against the dark sky is called a prominence.
Plages: A brighter, hotter patch in the Sun's chromosphere, visible in H-alpha light and the calcium K line. Plages are the chromospheric equivalent of faculae on the photosphere, as can be seen when an active region is near the limb. Faculae have a strong influence on the solar constant, and the more readily detectable (because chromospheric) plage areas traditionally are used to monitor this influence.

PREDICTIONS FOR 19 Apr 2014 10CM FLUX: 188 / AP: 005

Catania regions

COMMENT: Eleven sunspot groups were reported by NOAA today. NOAA ARs 2035,2036, and 2037 (Catania numbers 24, 25, and 26 respectively) maintain the beta-gamma configuration of the photospheric magnetic field. The strongest flare of the past 24 hours was the M1.0 flare peaking at 19:59 UT yesterday in the NOAA AR 2035 (Catania number 24). The flare was associated with an EIT wave and a weak coronal dimming, but the associated CME was narrow and is not expected to arrive at the Earth.
We expect further flaring activity on the C-level, especially in the NOAA ARs 2035 and 2037 (Catania numbers 24 and 26 respectively) as well as in the NOAA AR 2042 (no Catania number yet) that yesterday appeared from behind the east solar limb, with a good chance for an M-class event.

Since yesterday evening the Earth is situated inside a solar wind structure with an elevated interplanetary magnetic field magnitude (occasionally up to 10 nT). It may be a weak ICME or the compression region on the flank of an ICME that missed the Earth. The solar origin of this structure is not clear. The north-south magnetic field component Bz was not strong, so no significant geomagnetic disturbance resulted (K index stayed below 4). Currently the solar wind speed is around 380 km/s and the IMF magnitude is around 8 nT.
We expect quiet to unsettled (K index up to 3) geomagnetic conditions, with active geomagnetic conditions (K = 4) possible, but unlikely.

TODAY'S ESTIMATED ISN : 145, BASED ON 17 STATIONS.

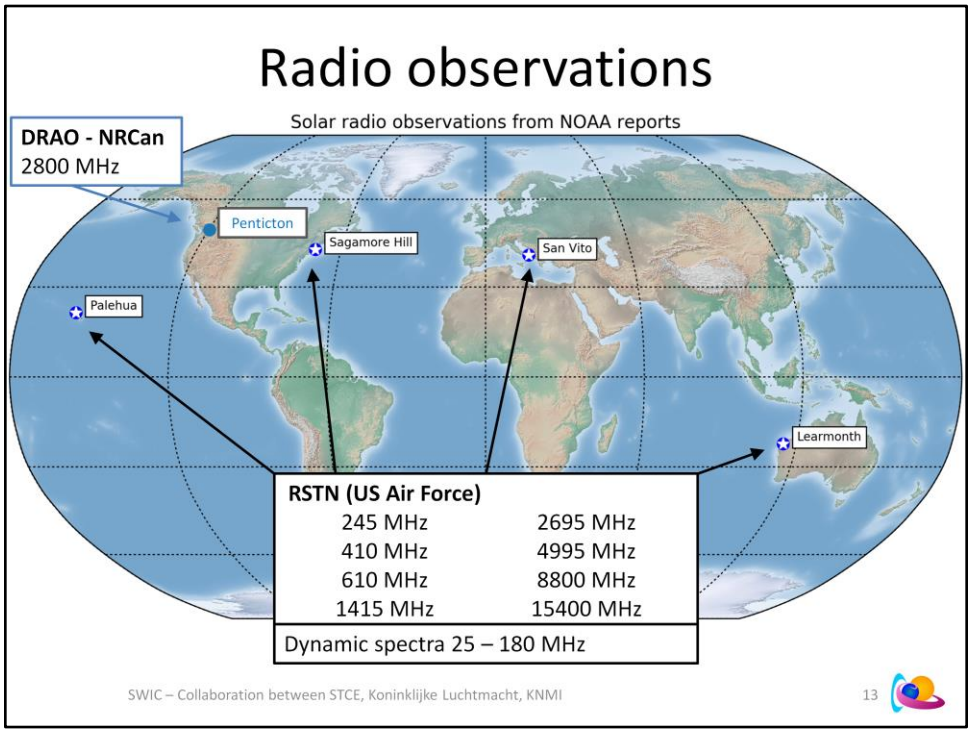
SOON: https://en.wikipedia.org/wiki/Solar_Observing_Optical_Network
The SOON observatories are operated by detachments of AFWA's 2nd Weather Group at the following sites: RAAF Learmonth, Western Australia, Australia
Holloman AFB, New Mexico, USA
San Vito dei Normanni Air Station, San Vito dei Normanni, Italy (contractor-run site)
Telescopes at Palehua, Hawaii and Ramey Air Force Base, Puerto Rico have been shut down.

ISOON: http://nsosp.nso.edu/isoon
The planned **Improved Solar Observing Optical Network** (**ISOON**) was intended to replace the current SOON network. As of 2012, ISOON only exists at a single pilot site on Kirtland Air Force Base. *Images will be available when the telescope is working again.*

Giersch et al. (2018) - Reanalysis of Solar Observing Optical Network Sunspot Areas
http://adsabs.harvard.edu/abs/2018SoPh..293..138G
SOON began operations in the mid-1970s with four sites (Holloman, New Mexico, USA; Ramey, Puerto Rico; Learmonth, Western Australia; and Palehua, Hawaii, USA) operating by 1980. In 1987, San Vito, Italy, became operational. … In 1996, the Palehua SOON equipment was returned to the National Solar Observatory at Sacramento Peak, New Mexico, to be used in the development of the Improved Solar Observing Optical Network (ISOON). However, **ISOON has never been deployed.** The Ramey site was closed in 2002. Thus, currently, there are only three SOON sites operating.

K-cor: http://download.hao.ucar.edu/d5/www/fullres/latest/latest.kcor.gif
Also at https://www2.hao.ucar.edu/cosmo/k-cor
Provides coronagraphic imagery. Large data gaps, limited time coverage during the day.

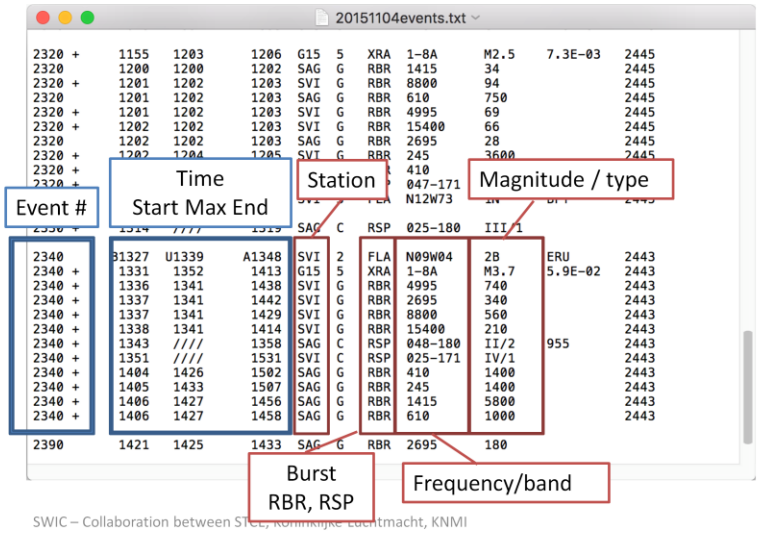


The flux at 2800 MHz (10.7 cm) is measured since 1946-1947 in Canada. First in Ottawa, then in 1962 in Algonquin Radio observatory, 250 km away from Ottawa, and since 1990 in Penticton. This is the longest time series reflecting the solar activity besides the Sunspot Index (to which it highly correlates). More info in : K. F. Tapping, "The 10.7 cm solar radio flux (F10.7)", Space Weather, 11, 394, 2013

DRAO: Dominion Radio Astrophysical Observatory
(https://www.nrc-cnrc.gc.ca/eng/solutions/facilities/drao.html)

The Radio Solar Telescope Network (RSTN) started its operation during the 1970s and is operated by the US Air Force. It consists of an ensemble of flux monitoring instruments and a set of radio spectrometers. Data are not available in real time, but reports of events are provided through NOAA. Data become available for scientists several months (or years!) afterwards.

NOAA radio event list



NOAA radio event list available at https://www.swpc.noaa.gov/products/solar-and-geophysical-event-reports

Station Abbreviations:
SVI: San Vito
SAG: Sagamore Hill
PAL: Palehua
LEA: Learmonth
PEN: Penticton

Type of Emission:
RBR: Radio Burst at fixed frequency
RSP: Radio Burst identified by its type in spectral data (radio sweep)

Frequency:
Frequency of the burst (in MHz) or frequency range in which it is observed

Magnitude/type:
For bursts at fixed frequency: magnitude above quiet Sun in Solar Flux Unit
For bursts reported by type: type/magnitude (1-3: weak to strong). If type II a speed is given in km/s (here 955 km/s)

Radio burst magnitudes

Typ. Quiet Sun values [SFU]

Frequency	Solar min.	Solar max. (Z=200)
245 MHz	10	15
410 MHz	25	35
610 MHz	30	45
1415 MHz	50	100
2695 MHz	70	200
2800 MHz	70	200
4995 MHz	100	200
8800 MHz	220	290
15400 MHz	580	650

How frequently bursts of a certain magnitude occur? 1 event every X days

f < 2000 MHz

Magnitude	Solar min.	Solar max.
1000	5 days	0.7 day
10000	34 days	4 days
100000	212 days	17 days

f > 2000 MHz

Magnitude	Solar min.	Solar max.
1000	38 days	6 days
10000	247 days	39 days
100000	1594 days	255 days

The left table reports typical values observed for the quiet Sun during minimum and maximum conditions. There can be lower and higher values but this is just to give an idea.

Values from the tables to the Right are derived from the paper by Nita et al. 2002. This gives in how many days on average a burst of a certain magnitude happens in each band. If we take a finer frequency band definition, the numbers can be different (see next slide).

Nita et al., 2002
The Peak Flux Distribution of Solar Radio Bursts
http://adsabs.harvard.edu/abs/2002ApJ...570..423N

Radio burst magnitude

100 MHz < f < 900 MHz

Magnitude	Solar Min.	Solar Max.
1000	6 days	0.75 days
10000	36 days	4 days
100000	223 days	17 days

1000 MHz < f < 1700 MHz

Magnitude	Solar Min.	Solar Max.
1000	65 days	12 days
10000	385 days	75 days
100000	2266 days	450 days

The right table shows more interesting statistics for a frequency band that covers GNSS services and air traffic radar and surveillance bands

Penticton

- Flux measurement at 2800 MHz (10.7 cm), 100 MHz bandwidth
- 3 times per day
- "official" value for the day is the one of 20:00 UT (local noon)
- Accuracy:
  - < 100 sfu: 1 sfu
  - > 100 sfu: 1% of flux
- Uncorrected for solar flares
- R-, S-, Q-component

Information from: K. F. Tapping, "The 10.7 cm solar radio flux (F10.7)", Space Weather, 11, 394, 2013 http://adsabs.harvard.edu/abs/2013SpWea..11..394T

Daily 10.7cm solar radio fluxes from Penticton at http://www.spaceweather.ca/solarflux/sx-4a-en.php

Daily radio fluxes (other wavelengths) at http://legacy-www.swpc.noaa.gov/ftpdir/lists/radio/rad.txt

Solar flux unit:
1 sfu = 10–22 W m–2 Hz–1

The Humain solar radio observatory efforts to develop 10.7cm radio flux measurements were halted after it became clear there was too much interference from Military instruments. http://www.sidc.be/humain/index.php

From Tapping (2013):
[7] The early measurements of solar centimetric emissions were made using relatively small antennas, having beams subtending solid angles larger than that subtended by the solar disk, so no determinations of the distribution of emission could be made on any routine basis. These spatially integrated emissions were categorized on the basis of their characteristic timescale of variation into three identifiable components: a rapidly varying or R component, comprising emissions varying over timescales in the second-minute range, perhaps as long as an hour. Slower variations were lumped into a slowly varying or S component. Extrapolation to zero activity suggested an underlying constant, base level, which became called the quiet sun, or Q component. The terms R and Q have fallen out of use, and these components are now known, respectively, as bursts and the quiet sun background emission. The slowly varying component originates primarily in active regions; its intensity is a measure of the overall level of solar magnetic activity and has a broad spectral peak at about 10 cm wavelength. The F10.7 values comprise contributions from the S component and the quiet sun background, and sometimes from radio bursts.

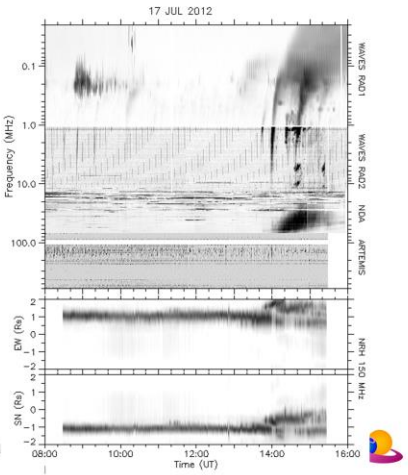
Nançay radio observations

- Nançay Radioheliograph
  - Imaging at several frequencies 150 – 450 MHz
- ORFEES spectrograph (130 – 1000 MHz)

https://realtime.obs-nancay.fr/orfees/

Archives: http://secchirh.obspm.fr



The Nançay Radioheliograph (NRH) provides 2d imaging of the solar corona between 150 and 450 MHz. It reveals radio emission associated with active regions (with sunspots) called noise storms. When an eruptive event occurs, imaging of different types of bursts (type II, type III, type IV etc…) is made. When solar activity is low, the quiescent corona becomes visible, showing the extent of large scale coronal structures (streamers, coronal holes etc…). The instrument is currently off for hardware upgrade.
The ORFEES spectrograph covers the band 130 – 1000 MHz and complements the imaging observations by providing the spectral type of the bursts. It's an instrument specifically built for space weather operations by a joint effort between the Paris Observatory and the French Air Force.

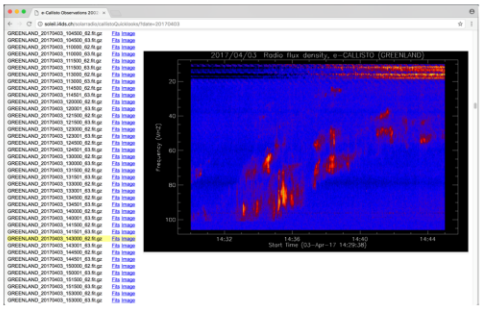
Callisto Network



http://soleil.i4ds.ch/solarradio/callistoQuicklooks/

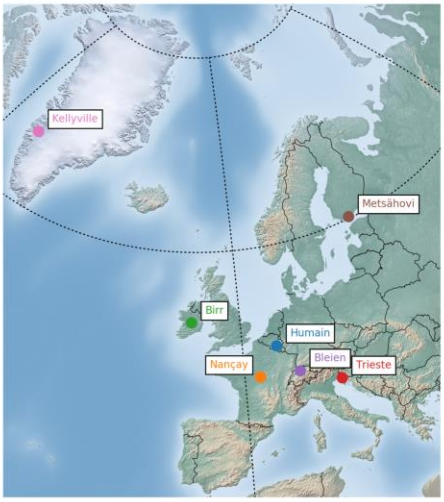
- Network of identical low cost analog receivers (~130 stations over the world)
- **http://www.e-callisto.org/**

- **Real time in Europe**
  - Birr Castle (Ireland): BIR
  - Humain (Belgium): HUMAIN
  - Bleien (Switzerland): BLEN5M, BLENSW
  - Trieste (Italy): TRIEST
  - Metsähovi (Finland): MRO
  - Kellyville (Greenland): GREENLAND

The e-Callisto network is a collection of individual Callisto receivers designed and set up by C. Monstein (ETH Zürich). Callisto receivers are based on an analog TV tuner (originally from Philips) that is controlled to scan the spectrum between 45 and 870 MHz. Up to 200 frequencies can be programmed in that range. Each station has its own set up (different antenna, front-end and frequency program). The stations mentioned here are the ones, in Europe, that are providing regular data to the network and are operated by institutional bodies.

Callisto stands for: Compound Astronomical Low cost Low frequency Instrument for Spectroscopy and Transportable Observatory
e-callisto stands for the network of callisto observatories.

European solar radio observatories
with real-time access

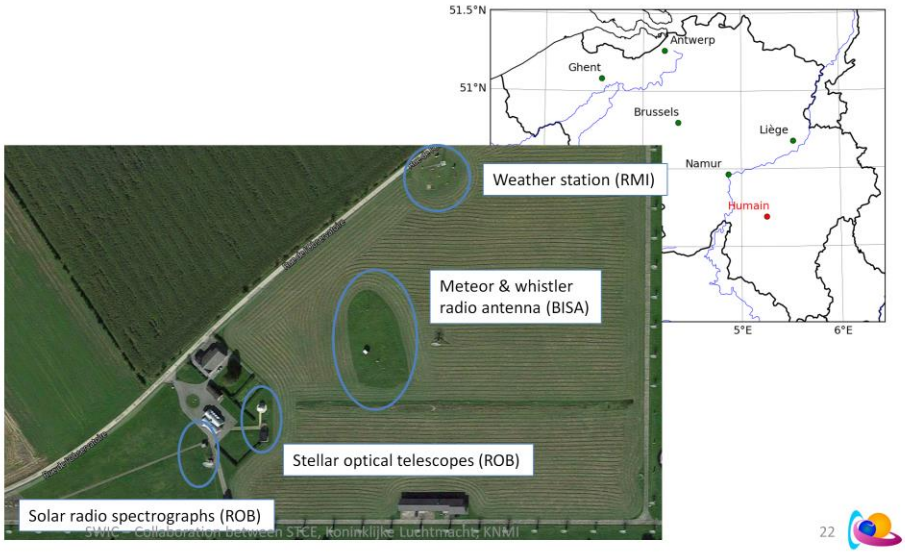


SWIC – Collaboration between STCE, Koninklijke Luchtmacht, KNMI 21

This map shows the locations of solar radio instruments operated by professional bodies (institutes, observatories etc…). Their data (essentially dynamic spectra) are available in real time or near real time

Available at e-Callisto at http://soleil.i4ds.ch/solarradio/callistoQuicklooks/

The Humain station



About 120 km south–east of Brussels

Humain: Solar instruments

- 6-m dish
- Automated operations, Sun tracking ~7h30 – 16h00 UT
- VHF antenna (piggy back)
- UHF antenna at focus

- VHF antenna (45 – 450 MHz)
  - Callisto receiver
  - ARCAS receiver
- UHF antenna (275 – 1495 MHz)
  - HSRS receiver

SWIC – Collaboration between STCE, Koninklijke Luchtmacht, KNMI 23

The ARCAS and HSRS receivers are based on commercial Software Defined Radio receivers. The RF signal is digitized and all operations needed to create the dynamic spectrum is made by programming on a control PC. The development of ARCAS and HSRS was made at ROB.

Callisto stands for: Compound Astronomical Low cost Low frequency Instrument for Spectroscopy and Transportable Observatory
ARCAS stands for Augmented Resolution Callisto Spectrometer - http://www.stce.be/news/369/welcome.html
HSRS stands for HUMAIN Solar Radio Spectrograph - http://www.stce.be/news/326/welcome.html

Humain: Solar instruments

- 6-m dish
- Automated operations, Sun tracking ~7h30 – 16h00 UT
- VHF antenna (piggy back)
- UHF antenna at focus

- VHF antenna (45 – 450 MHz)
  - Callisto receiver
  - ARCAS receiver
- UHF antenna (275 – 1495 MHz)
  - HSRS receiver

The ARCAS and HSRS receivers are based on commercial Software Defined Radio receivers. The RF signal is digitized and all operations needed to create the dynamic spectrum is made by programming on a control PC. The development of ARCAS and HSRS was made at ROB.

Callisto stands for: Compound Astronomical Low cost Low frequency Instrument for Spectroscopy and Transportable Observatory
ARCAS stands for Augmented Resolution Callisto Spectrometer - http://www.stce.be/news/369/welcome.html
HSRS stands for HUMAIN Solar Radio Spectrograph - http://www.stce.be/news/326/welcome.html

Humain: Solar instruments

	Callisto	ARCAS	HSRS
Type	Analog receiver	Digital	Digital

#----------#
DAILY BULLETIN ON SOLAR AND GEOMAGNETIC ACTIVITY from the SIDC
#----------#
SIDC URSIGRAM 40417
SIDC SOLAR BULLETIN 17 Apr 2014, 1304UT

SIDC FORECAST (valid from 1230UT, 17 Apr 2014 until 19 Apr 2014)
SOLAR FLARES : Active (M-class flares expected, probability >=50%)
GEOMAGNETISM : Quiet (A<20 and K<4)
SOLAR PROTONS : Quiet

PREDICTIONS FOR 17 Apr 2014 10CM FLUX: 180 / AP: 013
PREDICTIONS FOR 18 Apr 2014 10CM FLUX: 184 / AP: 007
PREDICTIONS FOR 19 Apr 2014 10CM FLUX: 188 / AP: 005

COMMENT: Eleven sunspot groups were reported by NOAA today. NOAA ARs 2035,2036, and 2037 (Catania numbers 24, 25, and 26 respectively) maintain the beta-gamma configuration of the photospheric magnetic field. The strongest flare of the past 24 hours was the M1.0 flare peaking at 19:59 UT yesterday in the NOAA AR 2035 (Catania number 24). The flare was associated with an EIT wave and a weak coronal dimming, but the associated CME was narrow and is not expected to arrive at the Earth.
We expect further flaring activity on the C-level, especially in the NOAA ARs 2035 and 2037 (Catania numbers 24 and 26 respectively) as well as in the NOAA AR 2042 (no Catania number yet) that yesterday appeared from behind the east solar limb, with a good chance for an M-class event.

Since yesterday evening the Earth is situated inside a solar wind structure with an elevated interplanetary magnetic field magnitude (occasionally up to 10 nT). It may be a weak ICME or the compression region on the flank of an ICME that missed the Earth. The solar origin of this structure is not clear. The north-south magnetic field component Bz was not strong, so no significant geomagnetic disturbance resulted (K index stayed below 4). Currently the solar wind speed is around 380 km/s and the IMF magnitude is around 8 nT.
We expect quiet to unsettled (K index up to 3) geomagnetic conditions, with active geomagnetic conditions (K = 4) possible, but unlikely.

TODAY'S ESTIMATED ISN : 145, BASED ON 17 STATIONS.

SWPC Kp index: https://www.swpc.noaa.gov/products/planetary-k-index
Dst index (Kyoto WDC): http://wdc.kugi.kyoto-u.ac.jp/dst_realtime/presentmonth/index.html
GOES Hp: https://www.swpc.noaa.gov/products/goes-magnetometer

https://www.swpc.noaa.gov/sites/default/files/images/u2/TheK-index.pdf

The A-index was invented because there was a need to derive some kind of daily average level for geomagnetic activity. Because of the non-linear relationship of the K-scale to magnetometer fluctuations, it is not meaningful to take averages of a set of K indices.

* GEO: GOES, SDO (inclined)
Advantages and disadvantages of SDO in GEO at https://sdo.gsfc.nasa.gov/mission/project.php
Orbit
The rapid cadence and continuous coverage required for SDO observations led to placing the satellite into an inclined geosynchronous orbit. This allows for a nearly-continuous, high-data-rate, contact with a single, dedicated, ground station.
Nearly continuous observations of the Sun can be obtained from other orbits, such as low Earth orbit (LEO). If SDO were placed into an LEO it would be necessary to store large volumes of scientific data onboard until a downlink opportunity. The large data rate of SDO, along with the difficulties in managing a large on-board storage system, resulted in a requirement of continuous contact.
The disadvantages of this orbit include higher launch and orbit acquisition costs (relative to LEO) and eclipse (Earth shadow) seasons twice annually, During these 2-3 week eclipse periods, SDO will experience a daily interruption of solar observations. There will also be three lunar shadow events each year from this orbit.
This orbit is located on the outer reaches of the Earth's radiation belt where the radiation dose can be quite high. Additional shielding was added to the instruments and electronics to reduce the problems caused by exposure to radiation. Because this is a Space Weather effect, SDO is affected by the very processes it is designed to study!

Crotser et al. (2004): SDO-EVE multiple EUV grating spectrograph (MEGS) optical design
http://adsabs.harvard.edu/abs/2004SPIE.5563..182C
The NASA Solar Dynamics Observatory (SDO), scheduled for launch in 2008, incorporates a suite of instruments including the EUV Variability Experiment (EVE). The EVE instrument package contains grating spectrographs used to measure the solar extreme ultraviolet (EUV) irradiance from 0.1 to 105 nm. The Multiple EUV Grating Spectrograph (MEGS) channels use concave reflection gratings to image solar spectra onto CCDs that are operated at -100°C. MEGS provides 0.1nm spectral resolution between 5-105nm every 10 seconds with an absolute accuracy of better than 25% over the SDO 5-year mission. MEGS-A utilizes a unique grazing-incidence, off-Rowland circle (RC) design to minimize angle of incidence at the detector while meeting high resolution requirements. MEGS-B utilizes a double-pass, cross-dispersed double-Rowland circle design. MEGS-P, a Ly-α monitor, will provide a proxy model calibration in the 60-105 nm range. Finally, the Solar Aspect Monitor (SAM) channel will provide continual pointing information for EVE as well as low-resolution X-ray images of the sun. In-flight calibrations for MEGS will be provided by the on-board EUV Spectrophotometer (ESP) in the 0.1-7nm and 17-37nm ranges, as well as from annual under-flight rocket experiments. We present the methodology used to develop the MEGS optical design.

SDO

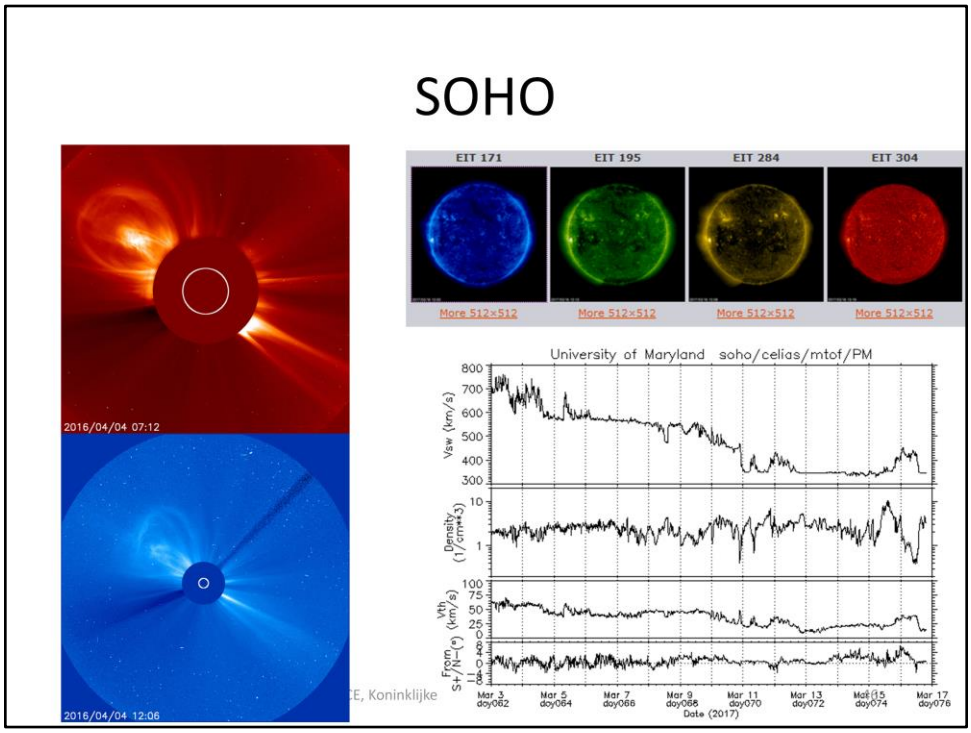
From P2SC: http://p2web.oma.be/about/sciencePayload

LYRA (**L**arge **Y**ield **RA**diometer, formerly **LY**man alpha **RA**diometer) is an ultraviolet irradiance radiometer that observes the Sun in four passbands, chosen for their relevance to solar physics, aeronomy and space weather. This instrument can also detect flares and analyze the atmospheric composition of the Earth.

SWAP (**S**un **W**atcher using **A**ctive Pixel System detector and Image **P**rocessing) is a small EUV telescope that images the solar corona with a bandpass around 17.4 nm, corresponding to a temperature of 1 million degrees. SWAP continues the systematic CME watch program of EIT at an improved cadence and monitors events in the lower solar corona that might be relevant for space weather.



SOHO: Solar and Heliospheric Observatory
Launched on 2 December 1995 and still observing from the L1 point!

EIT and coronagraphic imagery at https://sohowww.nascom.nasa.gov/data/realtime-images.html
The passbands and related temperatures are similar to SDO/AIA, with the 28.4 nm filter corresponding to 2 million degrees.

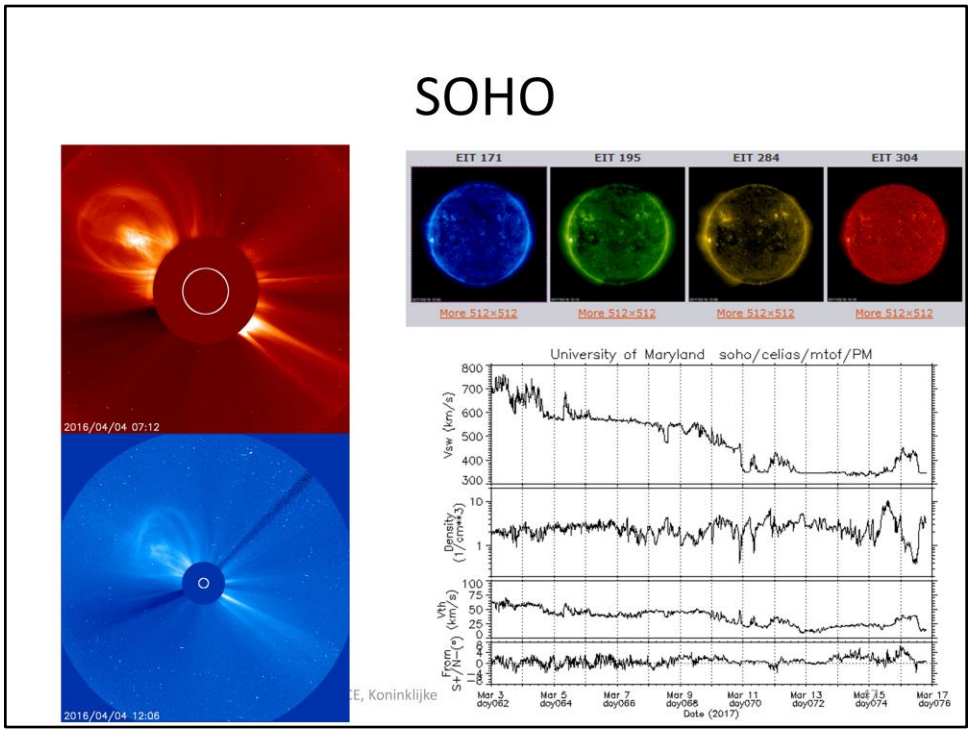
EIT: Extreme ultraviolet Imaging Telescope
CELIAS: Charge, Element, and Isotope Analysis System
MTOF: Mass Tome-of-Flight sensor
LASCO: Large Angle and Spectrometric Coronagraph
http://star.mpae.gwdg.de/

- C2 (1.5-6 solar radii)
- C3 (outer: 3-32 solar radii)

The C1 (inner: 1.1-3 solar radii) is no longer operational following SOHO's summer holidays in 1998:
https://lasco-www.nrl.navy.mil/index.php?p=content/intro
LASCO comprises of three telescopes (C1, C2 and C3), each of which looks at an increasingly large area surrounding the Sun. For the first year-and-a-half of the SOHO mission, all three instruments worked perfectly. However, in 1998 SOHO was accidentally "lost" in space after it received a bad command. The entire spacecraft lost power and essentially froze solid for several weeks. Eventually -- miraculously! -- the SOHO team were able to relocate the spacecraft, regain control and slowly power-up and thaw out the instruments. Sadly, the LASCO C1 camera was lost as a result of this but the rest of spacecraft came through almost completely unscathed! Eighteen years later -- and over twenty years since launch -- LASCO C2 and C3 (and most of the rest of SOHO!) continue to work extremely well, sending back images and data on a daily basis.



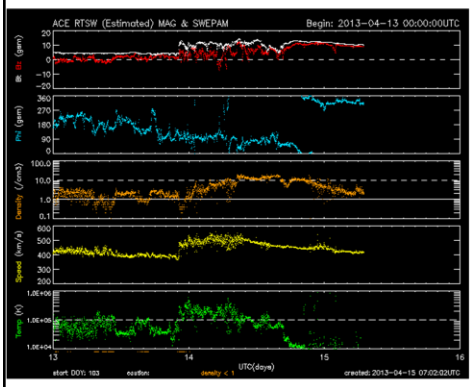
The weak CMEs/structures become better visible in difference imagery (one image subtracted from the other). Movies for the last 4 days can be found at https://sohowww.nascom.nasa.gov/data/realtime/mpeg/ (resp. LASCO C2 combo and LASCO C3 combo).

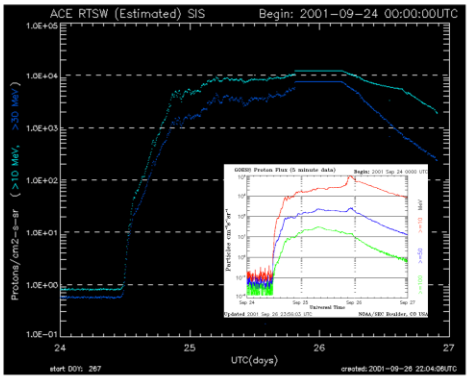
SOHO/LASCO is also a notorious comet chaser, discovering its 3000th comet on 14 September 2015.

SOHO has/had many other instruments, amongst which was the famous MDI (Michelson Doppler Imager) which made images of the Sun in “white light” as well as magnetograms. This program was terminated in 2011 as it was superseded by SDO/HMI. It was exceptionally switched on again for the Mercury transit 2016 (https://soho.nascom.nasa.gov/pickoftheweek/). The MDI archives are at http://soi.stanford.edu/

Descriptions of the other instruments can be found at https://sohowww.nascom.nasa.gov/about/instruments.html

ACE





ACE: Advanced Composition Explorer
http://www.srl.caltech.edu/ACE/

All data at NOAA/SWPC: https://www.swpc.noaa.gov/products/ace-real-time-solar-wind

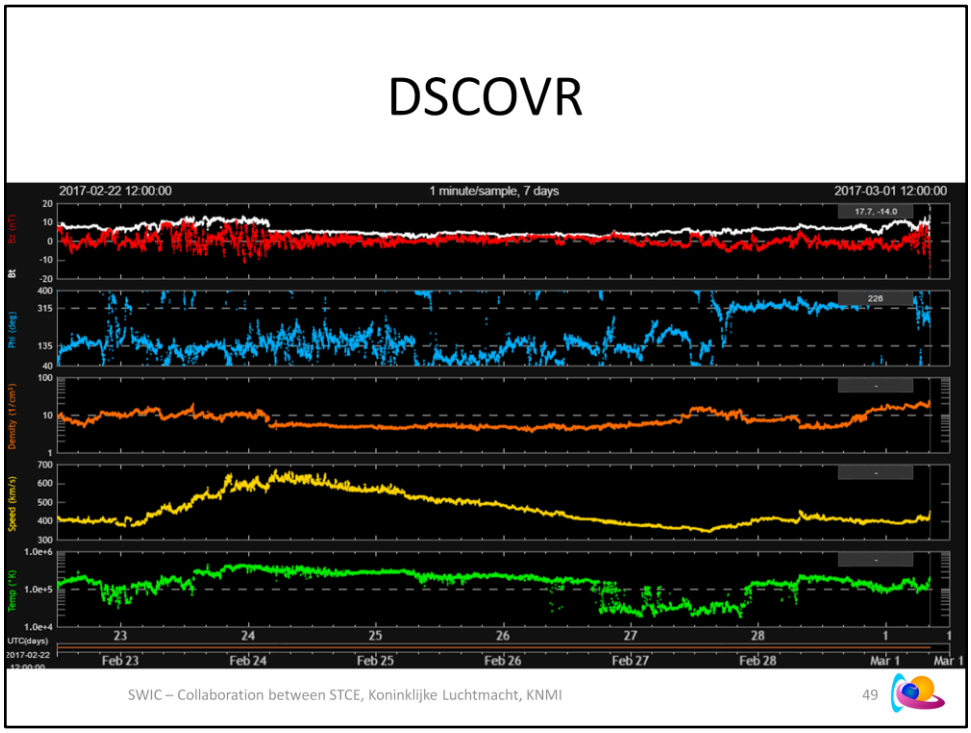
EPAM: Electron Proton Alpha Monitor
- measurements of low-energy electrons and protons

SWEPAM: Solar Wind Electron Proton Alpha Monitor
- measurements of solar wind density, speed and temperature

MAG: Magnetometer instrument
- Measurements of solar wind magnetic field

SIS: Solar Isotope Spectrometer
- Measurements of high-energy protons (>10 MeV, > 30 MeV)

ACE measurements of e.g. solar wind speed are sometimes unreliable in case of strong proton events, which is annoying when a CME arrives.
As of 27 July 2016, ACE is superseded by the DSCOVR satellite, and as such there's no longer a 24hr data coverage anymore.



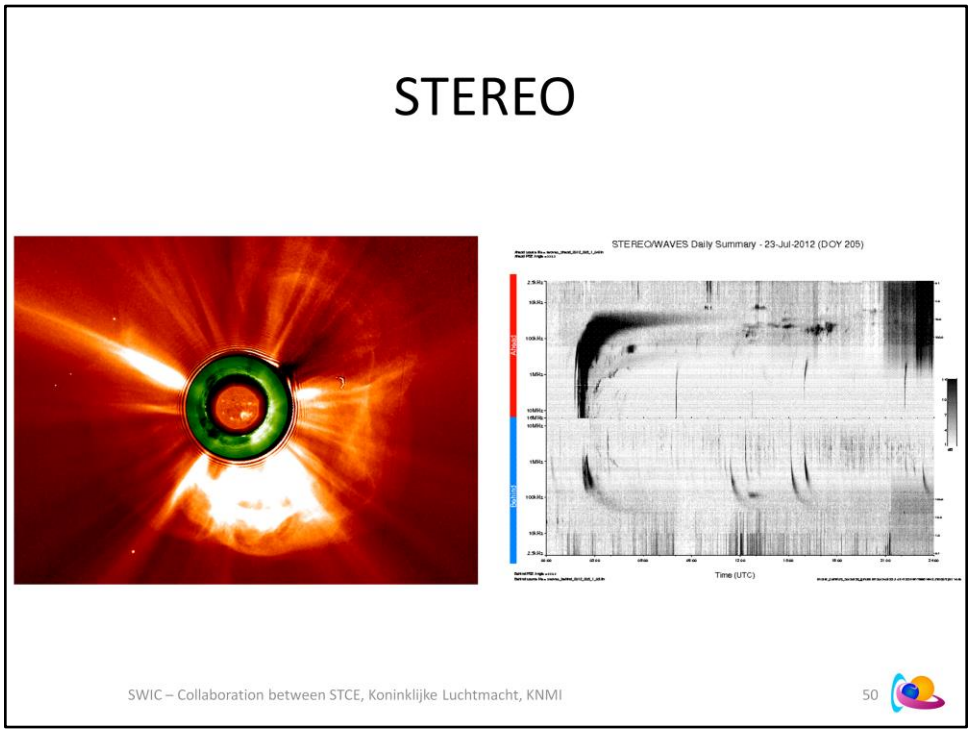
DSCOVR: Deep Space Climate Observatory
https://www.nesdis.noaa.gov/content/dscovr-deep-space-climate-observatory

Solar wind data are available at https://www.swpc.noaa.gov/products/real-time-solar-wind

From NOAA/SWPC: Real-Time Solar Wind (RTSW) data refers to data from any spacecraft located upwind of Earth, typically orbiting the L1 Lagrange point, that is being tracked by the Real-Time Solar Wind Network of tracking stations. The NOAA DSCOVR satellite became the operational RTSW spacecraft on July 27, 2016 at 1600UT (noon EDT, 10am MDT).
SWPC maintains the ability to instantaneously switch the spacecraft that provides the RTSW data. During times of outages in DSCOVR data or problems with the data, this page may instead display the data from the NASA/ACE spacecraft.

The two DSCOVR instruments for which data are available:
Faraday Cup (FC) of the Harvard Smithsonian Astrophysical Observatory(link is external)
Magnetometer (MAG) of the University of NASA Goddard Space Flight Center (link is external)

Note that DSCOVR is vulnerable to GCR, which introduces spurious measurement readings from time to time. The correctness of the values can be checked against the ACE data. More on this issue at http://www.nature.com/news/cosmic-rays-may-threaten-space-weather-satellite-1.20880
DSCOVR was in safe mode from 27 June 2019 till 02 March 2020 due to a technical glitch.
https://www.nesdis.noaa.gov/content/noaas-dscovr-satellite-operating-again



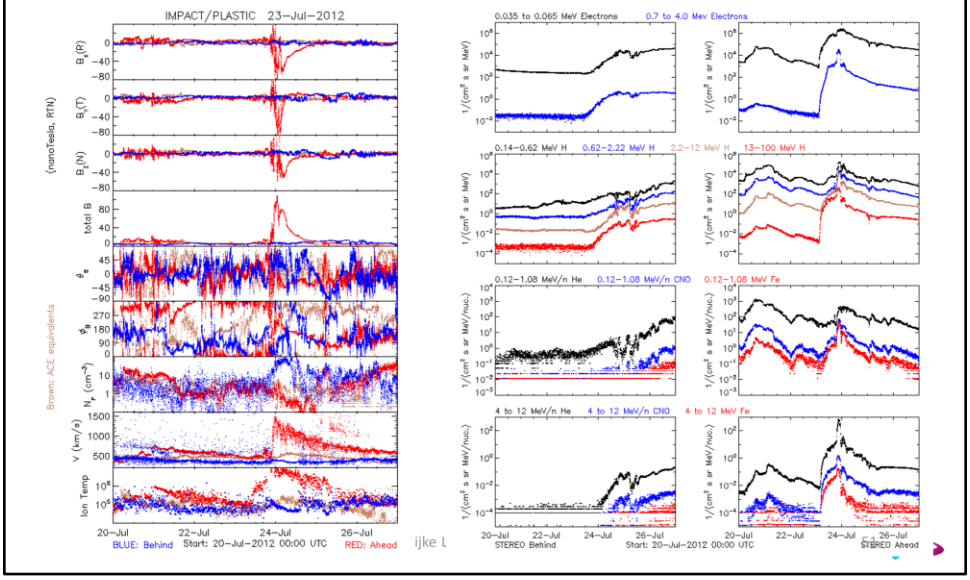
STEREO: Solar-Terrestrial Relations Observatory - SSC: STEREO Science Centre
All data and info are at https://stereo-ssc.nascom.nasa.gov/beacon/beacon_secchi.shtml

Twin spacecraft in sun orbit, one ahead (ST-A) of Earth in its orbit, the other trailing behind (ST-B). They were launched on 25 October 2006.
Contact with ST-B was lost on 1 October 2014 during a test. Re-establishing contact will be tried again in June 2017.
Both spacecraft have passed the anti-solar point in 2015, heading back to earth, but now ST-A is trailing the earth (not re-labelled).
Spacecraft will be close to earth again somewhere in 2023.

The main SWx advantages of the STEREO mission are
- A stereoscopic view of the Sun and CMEs, allowing e.g. a much better determination of the speed and direction of a CME.
- A direct view on the Sun's farside and its solar activity.
- Knowing 1-2 weeks in advance on the strength of CH HSS or active sunspot groups that may rotate over the east limb as seen from earth.

There are 4 main instrument packages:
- SECCHI: Sun Earth Connection Coronal and Heliospheric Investigation
    - EUVI: extreme ultraviolet imager (4 passbands: 171, 195, 284, 304 Angstrom or 17.1, 19.5, 28.4, 30.4 nm)
    - COR1/2: white-light coronagraphs (inner: 1.3 to 4 solar radii/outer: 2-15 solar radii)
    - HI1/2: heliospheric imagers
- PLASTIC: PLAsma and SupraThermal Ion Composition
    - Specifically interesting for proton and SEP events
- IMPACT: In-situ Measurements of Particles and CME Transients
    - Solar wind measurements
- SWAVES: STEREO Waves instrument
    - Track radiobursts from the Sun

STEREO



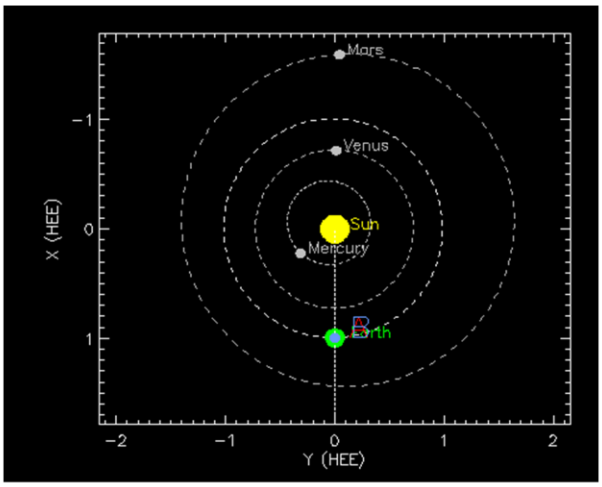
The example is from the Carrington-like event from 23 July 2012 (Sun's farside), showing:
Previous slide

- The EUVI304, COR1 and COR2 shortly after the maximum of the flare (but before the start of the proton event);
- The Type II and III radiobursts associated to the event (SWAVES)

This slide:

- The solar wind data from from PLASTIC/IMPACT for 7 days centered on 23 July 2012. Notice the strength of the event as observed by ST-A, and the lack of impact as observed by ST-B which was at the other side of the Sun
- The SEP data from the IMPACT instrument for 7 days centered on 23 July 2012. Notice the obvious differences between a well-connected (ST-A) and a poorly connected (ST-B) observer (much later, gradual and weaker with ST-B).

STEREO orbit (2006-2022)



https://stereo-ssc.nascom.nasa.gov/cgi-bin/make_where_gif

Exercise: Space-based instruments

- You want to have a clear view of any coronal holes that are visible on the Sun. Which instrument(s) would you use?
  - SOHO / LASCO C2
  - STEREO / Waves
  - SDO / AIA 193
  - GOES / XRS

Summary

- Both ground- and space-based data and imagery are used in SWx
  - Depends on the SWx user community and the purpose
- Multiple stations are a must
  - Back-up, cross-check & continuous monitoring
- Tools for analysis and forecasting are available
- Dashboards are available online
